

Second update of early emergences of moths at Selborne

This table continues the comparison (*antea*: 134) between my earliest records of non-hibernatory spring species in 1992-94 with those in 1995-1997. The m.v. light was run here on just over 320 nights during each year of the survey. Of the following 45 species, 33 arrived earlier in 1995-97 than in 1992-94. Two species had the same earliest date in both periods. 23 species were up to a month earlier than is usually expected.
